- ▶ Epidemics are often modelled using compartmental models.

- ▶ “mechanistic” reflection of disease spread.
- ▶ traditionally continuous-time and deterministic (ODEs).

$$\frac{dS(t)}{dt} = -\frac{\beta}{N} S(t)I(t), \quad \frac{dI(t)}{dt} = \frac{\beta}{N} S(t)I(t) - \gamma I(t), \quad \frac{dR(t)}{dt} = \gamma I(t).$$

- ▶ **susceptible dynamics** are key for model behaviour.

# EE and compartmental epidemic models (II)

- ▶ The endemic-epidemic model can be seen as a strongly simplified discrete-time stochastic SIR model.
  - ▶ see Bauer and Wakefield<sup>1</sup> for detailed derivations.
- ▶ But ultimately the endemic-epidemic model is **not** a fully mechanistic model.
  - ▶ susceptible dynamics are ignored.
  - ▶ many model elements are pragmatic rather than derived from first principles (e.g., negative binomial distribution).

---

<sup>1</sup>C Bauer and J Wakefield (2018): Stratified space-time infectious disease modelling, with an application to hand, foot and mouth disease in China. JRSSA.

- ▶ If you are looking for a (univariate) model with susceptible dynamics, **Time Series SIR** may be the right choice for you.

$$I_t \mid I_{t-1}, S_{t-1} \sim \text{NegBin}(\lambda_t, 1/I_{t-1})$$

$$\lambda_t = \frac{\beta}{N} S_{t-1} I_{t-1}^\alpha$$

$$S_t = S_{t-1} - I_t.$$

- ▶ R package: Becker and Grenfell (2017): `tsiR`: An R package for time-series Susceptible-Infected-Recovered models of epidemics. PLOS One.

- ▶ Technically, the EE model is a multivariate **I**nteger-valued **G**eneralized **A**utoregressive **C**onditional **H**eteroscedasticity (INGARCH) model.
- ▶ If you care about ergodicity, stationarity etc, there is a vast literature on INGARCH models.
- ▶ Several R packages exist:

**tscount: An R Package for Analysis of Count Time Series Following Generalized Linear Models**

Tobias Liboschik  
TU Dortmund University

Konstantinos Fokianos  
University of Cyprus

Roland Fried  
TU Dortmund University

**Inference for Network Count Time Series  
with the R Package PNAR**  The R Journal

*by Mirko Armillotta, Michail Tsagris, and Konstantinos Fokianos*

# What the EE model offers

- ▶ EE is **more pragmatic than full mechanistic models**.
  - ▶ simple base model facilitates multivariate extension.
  - ▶ latent susceptible dynamics are ignored.
  - ▶ simple maximum likelihood inference can be used.
- ▶ EE is **more tailored than generic count time series models**.
  - ▶ identifiability ensured by “semi-mechanistic” parameterizations.
  - ▶ complexity “spent” on epidemiologically relevant aspects.
- ▶ The EE model has a **robust and longstanding implementation** in the R package `surveillance`.

# Reminder: Multivariate model structure

- ▶ The multivariate **endemic-epidemic** model is defined as

$$Y_{rt} \mid \text{past} \sim \text{NegBin}(\mu_{rt}, \psi_r) \quad (1)$$

$$\mu_{rt} = \nu_{rt} + \phi_{rt} \times \sum_{r'=1}^N w_{r'r} \times Y_{r',t-1} \quad (2)$$

- ▶ As in surveillance within-region dynamics are given extra flexibility we often also write

$$\mu_{rt} = \underbrace{\nu_{rt}}_{\text{end}} + \underbrace{\lambda_{rt} \times Y_{r,t-1}}_{\text{ar}} + \underbrace{\phi_{rt} \times \sum_{r' \neq r} w_{r'r} \times Y_{r',t-1}}_{\text{ne}}. \quad (3)$$

- ▶ How do we handle all these parameters smartly?

- ▶ The EE framework accommodates the following epidemiologically meaningful mechanisms:
  - ▶ seasonality (and other external drivers).
  - ▶ simple but well-motivated mechanisms for spatial spread.
  - ▶ integration of social contact data.
  - ▶ encoding of generation times.
  - ▶ spatially smooth effects (random effects).

# Seasonality and covariates

- ▶ Reminder: the parameters  $\nu_{r,t}$ ,  $\lambda_{r,t}$  and  $\phi_{r,t}$  are modelled in a log-linear fashion to account for seasonality or other covariates, e.g.,

$$\log(\nu_{r,t}) = \alpha_i + \gamma \sin(2\pi t/52) + \delta \cos(2\pi t/52).$$

- ▶ Often it makes sense to share some parameters ( $\gamma, \delta$ ) across units  $r = 1, \dots, N$ , while others are unit-specific ( $\alpha_i$ ).

```
formula_end <- addSeason2formula(  
  ~0 + fe(1, unitSpecific = TRUE),  
  S = 1)
```

- ▶ Intuition: Seasonality and other covariates modify disease import and transmission ( $\approx$  reproductive numbers).

# The power law

- ▶ A simple spatial coupling (and the default in surveillance) is to set

$$w_{r'r} = \begin{cases} 1 & \text{if } r, r' \text{ are neighbours} \\ 0 & \text{else.} \end{cases}$$

- ▶ A smart way to allow dependences between indirect neighbours is a power law,

$$w_{r'r} \propto (o_{r'r} + 1)^{-\rho}.$$

- ▶ Weights are typically normalized such that  $\sum_{r'=1}^N w_{rr'} = 1$ .

```
formula_ne <- list(f = ~0 + fe(1, unitSpecific = TRUE),  
                  weights = W_powerlaw(maxlag = 5,  
                                       normalize = TRUE,  
                                       log = TRUE))
```

## Power law (II)

- ▶ Example: How does one district “distribute” its infectious pressure under the power law ( $\rho = 2.5$ )?

# Why a power law?

- ▶ Empirical evidence indicates that “the distribution of travelling distances decays as a power law.”
  - ▶ D Brockmann, L Hufnagel, T Geisel (2006): The Scaling Laws of Human Travel. Nature.
- ▶ In the EE framework, power laws have been found to outperform other (more complex) specifications.
  - ▶ S Meyer and L Held (2014): Power-law models for infectious disease spread. AOAS.
  - ▶ Geilhufe et al (2014): Power law approximations of movement network data for modeling infectious disease spread. Biometrical Journal.

# Social contact matrices

- ▶ When modelling spread across age groups rather than space, social contact data can be used to parameterize the  $w_{r',r}$ .<sup>2</sup>

- ▶ Side note: Pioneering work<sup>3</sup> came from U Hasselt!

<sup>2</sup>S Meyer and L Held (2017): Incorporating social contact data in spatio-temporal models for infectious disease spread. Biostatistics.

<sup>3</sup>Hens et al (2009): Estimating the impact of school closure on social mixing behaviour and the transmission of close contact infections in eight European countries. BMC Infectious Diseases.

- ▶ Using the `hhh4addon` package, the EE model can be extended to<sup>4</sup>

$$Y_{rt} \mid \text{past} \sim \text{NegBin}(\mu_{rt}, \psi_r) \quad (4)$$

$$\mu_{rt} = \nu_{rt} + \phi_{rt} \times \sum_{r'=1}^N \sum_{d=1}^D w_{r'r} \times u_d \times Y_{r',t-d}, \quad (5)$$

where  $u_1, \dots, u_D$  is the generation time / serial interval distribution.

---

<sup>4</sup>Bracher and Held (2020). Endemic-epidemic models with discrete-time serial interval distributions for infectious disease prediction. *IJF*.

## Generation times (II)

- ▶ Generation time distributions can be fixed based on literature estimates or estimated parametrically (?profile\_par\_lag), e.g.,

$$u_d = (1 - \pi)^{k-1} \pi$$

- ▶ Example: Dengue in Puerto Rico (Bracher and Held 2020).

# Spatial random effects

- ▶ For models with many strata and many parameters, spatially structured (CAR) random effects can be used.
- ▶ Example from Meyer et al<sup>5</sup>:

Figure 18: Maps of the estimated random intercepts.

<sup>5</sup>S Meyer et al (2017): Spatio-Temporal Analysis of Epidemic Phenomena Using the R Package surveillance. JSS.

# What is the EE model used for?

- ▶ The EE model was conceived as a generic tool to “*provide an adequate fit, reliable one-step-ahead prediction intervals*” and “*capture space–time dependence caused by the spatial spread of a disease over time*” (Held, Höhle, Hoffmann 2005).
- ▶ Over time it has been used for a variety of purposes (some anticipated, some not).

- ▶ Robert et al<sup>6</sup> use the EE framework to generate national and subnational-level forecasts of COVID-19 cases and deaths.

Image license: <http://creativecommons.org/licenses/by/4.0/>

<sup>6</sup>A Robert et al (2024): Predicting subnational incidence of COVID-19 cases and deaths in EU countries. BMC Infectious Diseases.

- ▶ Within the RespiNow Consortium, we use the EE model e.g., to predict weekly SARI hospitalizations in Germany:

## RESPINOW-Hub: Nowcasting of respiratory pathogens in Germany (Beta)

**Sprache / language**  
 Deutsch  English

**Data version**  
2024-06-05

**Disease / indicator**  
SARI (ICOSARI)

Nowcasts and predictions are updated on Thursdays or Fridays, depending on data availability.

**Stratification**  
 Bundesland  Age group

**Bundesland**  
Alle (Deutschland)

Not all time series are available per Bundesland and age group. When comparing age groups or Bundesland/er please note that the scales in the figure differ.

**Explanation of control elements**

This website is currently in a pilot phase and serves purely for scientific exchange. The analyses are not yet updated regularly. Not all displayed results were computed in real time.

**Brief explanation:** The black line shows the data as available at the time of last update of this website (usually Thursday / Friday). The most recent values of these data are typically incomplete and will still be corrected upwards. Coloured lines show the anticipated correction and, where applicable, the predicted future course.

**Particularities of the chosen data source:**

The interactive visualization works best under Google Chrome and is not optimized for mobile devices.

- ▶ Herzog et al<sup>7</sup> study the impact of measles vaccination coverage on the occurrence of measles.
- ▶ Model for bi-weekly measles counts  $Y_{rt}$  in 16 German states:

$$Y_{rt} \mid \text{past} \sim \text{NegBin}(\mu_{rt}, \psi_r)$$

$$\mu_{rt} = \nu_{rt} + \lambda_r \times X_{t-1}$$

$$\log(\nu_{r,t}) = \alpha_i + \gamma \sin(2\pi t/26) + \delta \cos(2\pi t/26).$$

$$\lambda_r = \beta_0 + \beta_1 \times \log(\text{proportion unvaccinated school starters in } r)$$

- ▶ Result: "... a significant association between estimated vaccination coverage at school entry and the overall incidence of measles'.<sup>7</sup>
- ▶ Data are available in surveillance.

---

<sup>7</sup>S Herzog et al (2011): Heterogeneity in vaccination coverage explains the size and occurrence of measles epidemics in German surveillance data. *Epi&Inf.*

- ▶ Grimée et al<sup>8</sup> study the impact of border closures between Switzerland and Italy by producing counterfactual scenarios.

# Estimation of local reproductive numbers

- ▶ Bauer and Wakefield (HMF disease) and Bracher and Held<sup>9</sup> (rotavirus) estimate local effective reproductive numbers  $R_t$ .
- ▶ In multivariate models (vector notation),

$$\mathbb{E}(Y_t) \mid \text{past} = \nu_t + \Phi_t Y_{t-1},$$

the largest eigenvalue of  $\Phi_t$  corresponds to  $R_t$ .

- ▶ Example:  $R_t$  of rotavirus in Berlin:

<sup>9</sup>Bracher and Held (2020): A Marginal Moment Matching Approach for Fitting Endemic-Epidemic Models to Underreported Disease Surveillance Counts. Biometrics.

- ▶ We will now run through the development of a simple multivariate model.
